#### **Abstract**

This paper provides evidence on the impact of major epidemics from the past two decades on income distribution. The pandemics in our sample, even though much smaller in scale than COVID-19, have led to increases in the Gini coefficient, raised the income share of higher-income deciles, and lowered the employment-to-population ratio for those with basic education compared to those with higher education. We provide some evidence that the distributional consequences from the current pandemic may be larger than those flowing from the historical pandemics in our sample, and larger than those following typical recessions and financial crises.

#### I. Introduction

As of November 30, 2020, deaths from the COVID-19 pandemic have reached about 1.4 million worldwide according to official statistics. This tragic cost has been accompanied by the upending of millions of other lives as governments take necessary steps to limit the spread of the virus. In the United States, for instance, evidence from a large-scale survey of households suggests that 40 million jobs were lost by late May, far more than were lost over the entire Great Recession of 2008-09 (Coibion, Gorodnichenko and Weber 2020). While the global job loss is more difficult to gauge, the decline in working hours thus far, which is easier to track in real-time, has been also unprecedented (ILO 2020).

While most income groups are adversely affected by the pandemic, it is possible that lower-income deciles and those with lower skills end up being disproportionately hurt. Indeed, there is already evidence of such effects, raising the prospect at least of a persistent increase in inequality in the absence of forceful policy interventions. Using data from a large-scale survey of U.K. households, Crossley, Fisher and Low (2020) show that those in the lowest quintiles of income and those from minority ethnic groups have experienced the largest job losses. Similarly, using transaction data from a large Fintech company, Hacioglu, Känzig and Surico (2020) and Surico, Känzig and Hacioglu (2020) document a surge in market income inequality in the United Kingdom since the beginning of the COVID-19 crisis. Aspachs et al. (2020), using high-frequency data on bank records, wages and public transfers for Spain, provide evidence of increasing income inequality due to severe job losses for low-income households.

The socio-economic impact of the pandemic, moreover, is not limited to income-related losses. Blundell (2020) documents adverse effects on health, education, labor market access and other socio-demographic indicators in United Kingdom. Similarly, using survey data, Aucejo et al. (2020) show that the pandemic is widening achievement gaps in higher education, with lower-income students being 55% more likely than their higher-income peers to delay graduation. There are also direct and immediate effects from lower-income groups being more prone to the disease: Schmitt-Grohe, Teoh and Uribe (2020) find that, in New York City, poor people are less likely to test negative for COVID-19: moving from the richest to the poorest zip codes is associated with a decline in the fraction of negative test results from 65 to 38 percent.

To shed light on possible short and medium-term distributional impacts of COVID-19, this paper uses data from major epidemics (referred to interchangeably below as pandemics) over the past two decades and their links to: income inequality; income shares of the top and bottom deciles; and employment prospects of people with low education levels (using educational attainment as a proxy for skills). Our results justify the concern that COVID-19 could end up exerting a significant impact on inequality. Past pandemics, even though much smaller in scale, have led to increases in the Gini coefficient, raised the income shares of higher-decile income groups, and lowered the employment-to-population ratio of those with basic education compared to those with higher education. Our evidence suggests that the distributional consequences from the current pandemic may be larger than those flowing from the historical pandemics in our sample, and larger than those following typical recessions and financial crises.

This paper relates to two main strands of literature. The first is the literature on the economic effects of pandemics: Atkeson 2020; Barro et al. 2020; Eichenbaum et al. 2020; Jordà et al. 2020; Ma et al. 2020a. This literature provides evidence of large and persistent effects on economic activity from pandemics. Ma et al. (2020a) examined the same set of episodes used here and found that real GDP is 2.6% lower on average across 210 countries in the year the outbreak is officially declared and remains 3% below the pre-shock level five years later. The second strand of the literature relates to the effects of crises and recessions on inequality and employment including of the less skilled and youth: Camacho and Palmieri 2019; de Haan and Sturm 2017.

The remainder of the paper is structured as follows. Section II describes our data and econometric method and Section III presents our results. The last section concludes and outlines avenues for future work on this topic.

#### II. DATA AND ECONOMETRIC METHOD

#### *Income distribution*

Our data on various measures of distribution come from three sources. Table A1 in the Online Appendix provides summary statistics on the variables used in the analysis.

• Gini coefficients are from the Standardized World Income Inequality Database (SWIID 8.3), which combines information from the United Nations World Income Database (UNWIDER) and

the Luxembourg Income Study (LIS). SWIID provides comparable estimates of market and net income inequality for 177 countries from 1960 to the present (Solt 2009).<sup>1</sup>

- Income shares by decile are from the World Bank's World Development Indicators. This source provides internationally comparable statistics for a large number of economies; however, for many countries the time series is rather short, so in the end our results on income deciles are for a limited sample of 64 countries from 1981 to the present.
- Comparable data on employment by skill levels are difficult to obtain for a large group of countries. The ILO notes that "statistics on levels of educational attainment remain the best available indicators of labor force skill levels." Hence, we use ILO data on employment-to-population ratios for different education levels—advanced, tertiary and basic—for a limited sample of 76 countries from 1990 to the present.

#### Pandemic events

As in Ma et al. 2020a, we focus on five major events: SARS in 2003; H1N1 in 2009; MERS in 2012; Ebola in 2014; and Zika in 2016. The countries affected by each event are presented in Table A2 and Table A3 in the Online Appendix (we exclude countries for which income inequality data are unavailable). We construct a dummy variable, the pandemic event, which takes the value 1 when the WHO declares a pandemic for the country and 0 otherwise. Our baseline results estimate the evolution of inequality in the aftermath of the pandemic event. However, we also take account of how the severity of the pandemic affects distributional outcomes. The most widespread pandemic in our sample is H1N1 (Swine Flu Influenza), with more than 6,000,000 confirmed cases across 148 countries (about 1 case per thousand people) and about 19,000 fatalities. While H1N1 spread across all regions, the other four events are mostly confined to specific regions: (i) SARS and MERS in Asia; (ii) Ebola in Africa and (iii) Zika in the Americas (Figure A1). In terms of average mortality rates (deaths/confirmed cases), MERS and SARS were the most severe, followed by Ebola and H1N1.

<sup>&</sup>lt;sup>1</sup> We use data from SWIID as baseline because of the larger country and time coverage compared to other commonly-used sources, such as WIDER and POVCAL. In the robustness checks, we show that our results hold when using data from these alternative sources.

# Empirical methodology

To estimate the distributional impact of pandemics, we follow the method proposed by Jordà (2005) and estimate impulse response functions directly from local projections:

$$y_{i,t+k} = \alpha_i^k + \gamma_t^k + \beta^k D_{i,t} + \theta^k X_{i,t} + \varepsilon_{i,t+k}$$
(1)

where  $y_{i,t}$  is a distribution variable (e.g. the Gini coefficient) for country i in year t;  $\alpha_i$  are country fixed effects, included to take account of differences in countries' average income distribution;  $\gamma_t$  are time fixed effects, included to take account of global shocks such as shifts in oil prices or the global business cycle;  $D_{i,t}$  is a dummy variable indicating a pandemic event in country i at year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable and of the pandemic dummy. In the baseline, we do not include other controls on the grounds that the date of the pandemic event is likely to be exogenous to the economy. Indeed, as shown in Table A5 of the Online Appendix, the dates of pandemic events are uncorrelated with past levels and changes of inequality. Nonetheless, we consider, subsequent to presenting our baseline findings, possible concerns arising from our empirical strategy (i.e. omitted variable bias and reverse causality): we present a wide range of robustness checks including an Augmented Inverse Probability Weighting (AIPW) estimation as in Jordà and Taylor (2016) and an Instrumental Variable approach.

Equation (1) is estimated for an unbalanced panel of 177 countries over the period 1960-2019, for each horizon (year) k=0,...,5. Impulse response functions are computed using the estimated coefficients  $\beta^k$ , and the confidence bands associated with the estimated impulseresponse functions are obtained using the estimated standard errors of the coefficients  $\beta^k$ , based on robust standard errors clustered at the country level.

#### III. DISTRIBUTIONAL IMPACTS OF PANDEMICS

#### Impacts on Gini coefficients

Figure 1 shows the estimated dynamic response of net Gini to a pandemic event over the five-year period following the event, together with the 90 percent confidence interval around the

point estimate. Table A4 reports the associated regressions. Pandemics lead to a persistent increase in inequality with a peak effect of about 0.4 five years after the pandemic. Given that the Gini is a slow-moving variable, these are quantitatively important effects: peak effects correspond to about a 1½ standard deviation of the average change of the Gini in the sample.<sup>2</sup>

The Online Appendix reports our robustness checks. First, we check the sensitivity of our results to alternative measures of inequality, such as the market Gini from SWIID and the Ginis from the World Bank POVCAL database—which covers the period 1978-2017 and includes 171 countries (1711 observations)—and the World Institute for Development Research WIDER (WIID) dataset—which covers the period 1948-2014 and includes 166 countries (1386 observations). The results in Figures A2-A3 confirm our main findings: results based on the POVCAL/WIDER datasets point to even higher medium-term effects: about 1.5-2.0—statistically significant at 1 and 5% level, respectively.

Second, as an alternative empirical strategy, we present results from the autoregressive distributed lag (ADL) approach of Romer and Romer (2010) and Furceri, Loungani and Ostry (2019). Third, since the episodes in our sample occurred in the latest two decades, we replicate the analysis using a restricted sample that begins in 1995. Fourth, in order to mitigate omitted variable bias, we include several control variables that could be related to inequality—such as proxies for the level of economic development, demographics, measures of trade and financial globalization and country-specific time trends. The results presented in Figures A4-A7 of the Online Appendix are similar to, and not statistically different from, the baseline.

We also checked the validity of the *parallel trend assumption* in the evolution of inequality before the pandemic between countries by running a placebo test. Reassuringly, the impulse response functions obtained by attributing randomly pandemic dates across the whole sample do not point to significant results (Figure A8). Finally, in order to further address endogeneity, we adapt the approach proposed by Jordà and Taylor (2016) to estimate the causal effect of the occurrence of austerity, and we use the Augmented Inverse Probability Weighting

<sup>&</sup>lt;sup>2</sup> The Gini coefficient on net income has increased cumulatively by about 10 percent in the US during the period 1980-2010 (from about 0.45 in 1980 to about 0.5 in 2010—see, among others, Coibion et al. 2017).

<sup>&</sup>lt;sup>3</sup> Data are taken from the All the Ginis (ALG) Database (https://stonecenter.gc.cuny.edu/research/all-the-ginis-alg-dataset-version-february-2019/). See Jenkins (2015) and Chapter 2 in Ostry, Loungani and Berg (2019) for a discussion of the pros and cons of SWIID data set relative to others.

(AIPW) estimation based on a Probit model of the occurrence of pandemics on the level of GDP and its growth rate, average country temperature, total health expenditures, government final expenditures, mortality rate, and other controls. <sup>4</sup> The results reported in Table A6 of the Online Appendix point to a statistically significant impact of pandemics on income inequality with effects being quantitatively close to those shown in Figure 1.

### Impact on other indicators of distribution

To shed light on the channels through which pandemics affect inequality, we explore the impact of pandemic events on income shares and employment outcomes by educational groups. These results are for a smaller set of countries given data availability.

The results for the impact of pandemics on the income shares held by the top (bottom) 20% are shown in Figure 2. It is evident that the impact is to raise the shares of the upper-income quintile and reduce those of the lower-income quintile. The impacts are statistically significant and quantitatively sizable. For instance, the share of income going to the top two deciles is 46 percent on average; five years after the pandemic, this share increases to nearly 48 percent. The share of income going to the bottom two deciles is 6 percent; five years after the pandemic, this share falls to 5.5 percent. We find similar effects when looking at the top (bottom) 10 and 40 percent (Figure A9 in the Online Appendix).

Figure 3 shows the disparate impact on the employment of people with different levels of educational attainment. Those with non-basic levels of education are scarcely affected, whereas the employment to population ratio of those with basic levels of education falls significantly, by more than 5 percent in the medium term—the effect is statistically significant at 5 percent.

# Pandemics vs. financial crises and other recessions

Are pandemics different from other recessions and crises? To answer this question, we augment our framework to include financial crises (taken from Laeven and Valencia 2019) and recession episodes—defined as years of negative real GDP growth (rather than in terms of output gaps, which are poorly measured in the case of developing countries). This exercise also allows

<sup>&</sup>lt;sup>4</sup> See the Online Appendix for a detailed description of this approach. Table A5 reports the Probit regression results. As shown in the table, the dates of pandemic events are uncorrelated with past levels and changes in inequality.

us to address the concern that some pandemic events in our sample may have occurred also during a period of crisis or recession. We estimate the following equation:

$$y_{i,t+k} - y_{i,t-1} = \alpha_i^k + \gamma_t^k + \beta^k D_{i,t} + \vartheta^k C_{i,t} + \theta^k M_{i,t} + \varepsilon_{i,t+k}$$
(2)

where C denotes the year of occurrence of a financial crisis or a year in which growth was negative, and M includes our earlier set of control variable X augmented by two lags of the financial crisis or recession dummy.  $^5$ 

The results in Figure 4 suggest that the distributional effects of pandemics are larger than those associated with financial crises or recessions: financial crises do not have a significant effect on inequality, and the Gini increases by about 0.05 following a typical recession—compared to more than 0.4 for pandemics. We find similar results when looking at income shares. While recessions seem to result in higher top income shares, top shares tend to decline in the medium term following a financial crisis (see Figure A11)—consistent with the fact the financial income tends to be highly concentrated in the upper part of the income distribution. Finally, the medium-term effects on the employment to population ratio of those with basic education falls significantly in all types of crises, suggesting that the difference in distributional effects between pandemics and other recessions is not due to this channel (see Figure A12).

Heterogeneity across episodes depend on the severity of pandemics

The average response of inequality to pandemic events may mask significant heterogeneity across episodes, based on the severity of the pandemic event, both in terms of confirmed cases and its economic effects. To probe further, we use two approaches. In the first,

<sup>&</sup>lt;sup>5</sup> Oua litatively similar results are obtained including financial crises and recessions at the same time.

<sup>&</sup>lt;sup>6</sup> This result is consistent with Camacho and Palmieri (2019) who did not find significant positive impacts of economic downturns and financial crises on income distribution. Consistent with the insignificant effect of financial crises on inequality, we also find that the effect of the H1N1 pandemic during the Global Financial Crisis is lower than that in other pandemic episodes (see Figure A10).

<sup>&</sup>lt;sup>7</sup> Income comprises labor, business financial income and transfers.

we replace pandemic dummy with a continuous variable using the information of the number of cases (Emmerling et al., forthcoming). Specifically, we estimate the following equation:

$$y_{i,t+k} = \alpha_i^k + \gamma_t^k + \beta_c^k \log_{10} \left( 1 + \frac{1000 \cdot confirmed\_cases_{i,t}}{population_{i,t}} \right) + \theta^k X_{i,t} + \epsilon_{i,t}^k$$
 (3)

While use of this continuous variable has the advantage of differentiating episodes based on their severity, it has two important drawbacks. First, it may be more prone to reverse causality as higher initial levels of inequality may increase the number of infections due to the higher economic and health vulnerability of marginalized people. Second, measurement errors related to total cases detected is likely to be non-negligible. To address these concerns, we resort to an instrumental variable approach. Following Nunn and Quian (2014), our Instrumental Variable (IV) approach consists of interacting a time-varying global term and a constant country-specific term. The global term is a dummy variable that takes the value of 1 for all countries in the years of pandemic outbreaks. The country-term we consider captures the factors affecting the severity of the pandemic. For this purpose, we consider the average temperature. As shown in several recent studies (i.e. Ma et al, 2020b; Ujiie et al. 2020), temperature is an important driver of the evolution of pandemics and it can reasonably be assumed to be exogenous.<sup>8</sup>

In the second approach, we estimate the following equation:

$$y_{i,t+k} - y_{i,t-1} = \alpha_i^k + \gamma_t^k + F(z_{it}) \left[ \beta_L^k D_{i,t} + \theta_L^k X_{i,t} \right] + \left( 1 - F(z_{it}) \right) \left[ \beta_H^k D_{i,t} + \theta_H^k X_{i,t} \right] + \varepsilon_{i,t+k}$$
with  $F(z_{it}) = \frac{exp^{-\gamma z_{it}}}{(exp^{-\gamma z_{it}})}, \quad \gamma = 3.5$  (4)

where z is an indicator of the severity of the pandemic (which is either the ratio of confirmed cases to population, or GDP growth), normalized to have zero mean and a unit variance. The weights assigned to each regime vary between 0 and 1 according to the weighting function F(.), so that

<sup>&</sup>lt;sup>8</sup> See the Online Appendix for a detailed description of this approach.

 $F(z_{it})$  can be interpreted as the probability of being in a given state of the pandemic. The coefficients  $\beta_L^k$  and  $\beta_H^k$  capture the distributional impact of a pandemic event at each horizon k in cases of mild pandemics in terms of cases-to-population ratio (or alternatively, higher output growth)  $(F(z_{it}) \approx 1 \text{ when } z \text{ goes to minus infinity})$  and extremely severe pandemic events in terms of cases-to-population ratio (or alternatively, lower output growth)  $(1 - F(z_{it}) \approx 1 \text{ when } z \text{ goes to plus infinity})$ , respectively— $F(z_{it})$ =0.5 is the cutoff between severe and weak pandemic event. We choose  $\gamma = 3.5$ , following Tenreyro and Thwaites (2016).

The results in Figure 5 show that the distributional effect of pandemic events varies with their severity. Using the continuous variable instead of a (0-1) dummy, the results point to larger effects of pandemics on inequality as case-to-population ratios increase: a one percent increase in the measure of severity implies a rise in net Gini of about 0.4 (Figure 5 -Panel A). In other words, the effect of an *average pandemic*—based on the average infection rate in our dataset (0.80 cases per 1000 inhabitants)—is associated with a medium-term increase in the net Gini of about 0.1. These effects imply that, as of November 30<sup>th</sup>, COVID-19 would lead to a medium-term increase in the Gini of about 0.5 (as of November 30<sup>th</sup>, 2020, the pandemic counted on average 7.5 cases per 1000 inhabitants, with a maximum rate of about 52 infections per 1000). The IV results confirm the adverse distributional effects of pandemics, with the magnitude of the coefficient significantly larger than the corresponding OLS.

The results obtained from estimating equation (3) show that for episodes associated with a larger number of cases relative to population (such as Croatia, H1N1, 2009), the effect is statistically significant and larger than the average effect shown in Figure 1 (the medium-term effect on Gini increases from 0.4 to about 0.8), while it is not statistically different from zero for episodes associated with small outbreaks (such as Philippines, SARS, 2003) (Figure 5 – Panel B). Similarly, the results in Panel C show that the medium-term effect is larger (about 0.7) in episodes associated with low growth (such as Korea, MERS, 2012), while it is not statistically different from zero for episodes associated with high growth (such as China, H1N1, 2009). 10

<sup>&</sup>lt;sup>9</sup> On this point see also Emmerling et al. (forthcoming).

<sup>&</sup>lt;sup>10</sup> The F-test of the difference between the estimations in the case of low and high regime of the interaction variable with the pandemic dummy are shown in Table A7 in the Online Appendix. Furceri, Loungani, Ostry and Pizzuto (2021) show that the response of income inequality to pandemics a lso depends on fiscal policy: the rise in inequality is higher when fiscal policy is tighter, while when the fiscal response is supportive, inequality barely increases.

#### IV. CONCLUSION

The COVID-19 crisis is already showing how the more vulnerable socio-economic groups suffer from a greater risk of financial exposure, greater health risks, and worse housing conditions during the lockdown period. These factors may exacerbate inequalities.

Our paper explores this possibility by providing evidence on the impact of pandemics and major epidemics from the past two decades on income distribution. Our results justify the concern that, in the absence of supportive policies to protect the vulnerable, the pandemic could end up exerting a significant impact on inequality: past events of this kind, even though much smaller in scale, have led to increases in the Gini coefficient, raised the income shares accruing to the higher deciles of the income distribution, and lowered the employment-to-population ratio for those with basic education compared to those with higher education. In addition, the result that the impact of past pandemics on inequality has been more greater in the more severe ones (both either in terms of number of cases or the output effects of the pandemic) suggests that the distributional consequences of COVID-19 may be larger than those following earlier pandemics in our sample, all else equal.

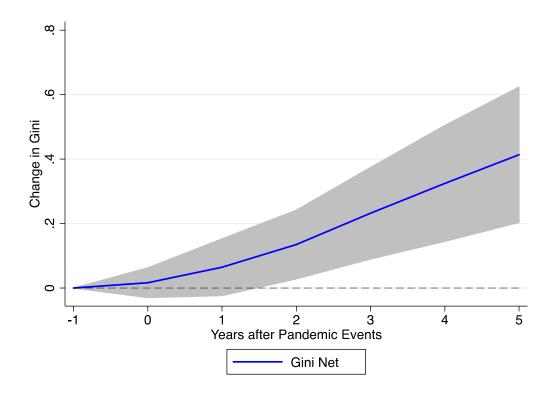

Our results leave several questions for future research. First, the distributional effects of pandemic events are likely to vary considerably across countries, depending on country-specific characteristics, initial income distribution, the stringency of containment measures as well as the policy response. Second, there is growing evidence that the economic effects of COVID-19 may also vary between different segments of the population including by race, age, and gender. Third, the human cost of pandemics is also sadly higher in low-income groups, which are more prone to diseases and have often more limited access to health services. These issues need attention.

FIGURE 1. IMPACT OF PANDEMICS ON NET GINI

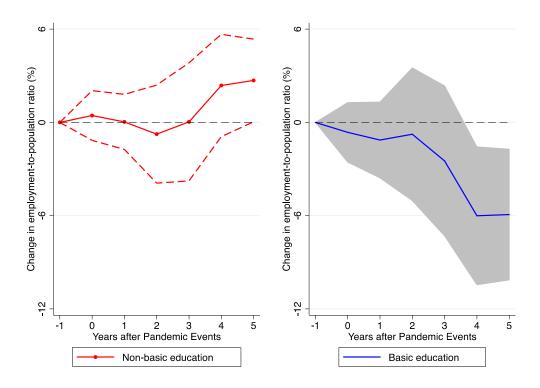

Notes: Impulse response functions are estimated using a sample of 177 countries over the period 1960-2019. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) a fter pandemic events; t=0 is the year of the pandemic event. Estimates based on  $y_{i,t+k} = \alpha_i^k + \gamma_t^k + \beta^k D_{i,t} + \theta^k X_{i,t} + \varepsilon_{i,t+k}$ .  $y_{i,t}$  is the Gini coefficient for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that affects country i in year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable and two lags of the pandemic dummy. See Table A2-A3 in the Online Appendix for the full list of pandemic events.

FIGURE 2. IMPACT OF PANDEMICS ON SHARES OF INCOME

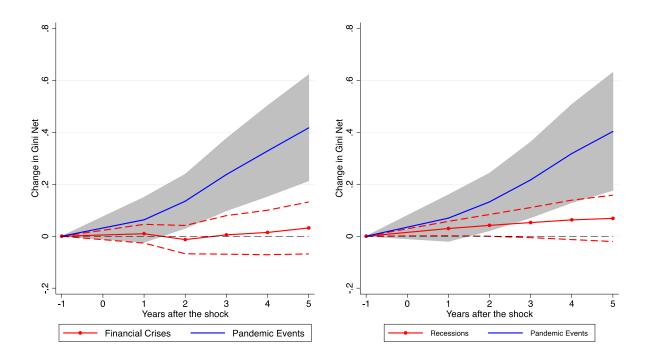

Notes: Impulse response functions are estimated using a sample of 64 countries over the period 1981-2017. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) a fter pandemic events; t=0 is the year of the pandemic event. Estimates are based on  $y_{i,t+k}-y_{i,t-1}=\alpha_i^k+\gamma_t^k+\beta^kD_{i,t}+\theta^kX_{i,t}+\varepsilon_{i,t+k}.y_{i,t}$  is the log of the income share held by the top (bottom) 20% for country i in year t;  $\alpha_i$  are country i in year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable and the pandemic dummy. See Table A2-A3 in the Online Appendix for the full list of pandemic events.

FIGURE 3. IMPACT OF PANDEMICS ON EMPLOYMENT-TO-POPULATION RATIO, BY EDUCATION LEVEL

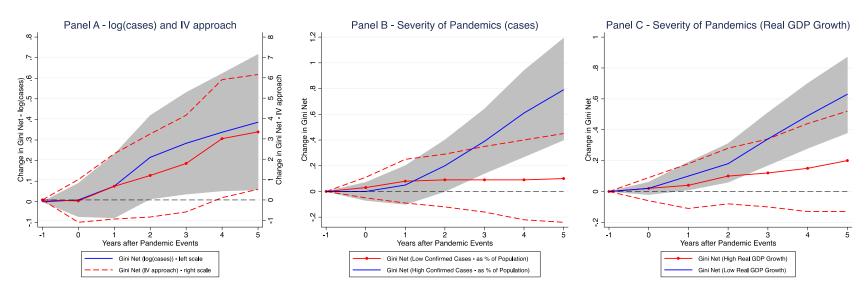

Notes: Impulse response functions are estimated using a sample of 76 countries over the period 1990-2017. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) a fter pandemic events; t=0 is the year of the pandemic event. Estimates are based on  $y_{i,t+k}-y_{i,t-1}=\alpha_i^k+\gamma_t^k+\beta^kD_{i,t}+\theta^kX_{i,t}+\varepsilon_{i,t+k}$ ,  $y_{i,t}$  is, in turn, the log of employment-to-population ratio by education level for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that a ffects country i in year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable and the pandemic dummy. See Table A2-A3 in the Online Appendix for the full list of pandemic events.

FIGURE 4. IMPACT OF PANDEMICS VS. FINANCIAL CRISES AND OTHER RECESSIONS

Notes: Impulse response functions are estimated using a sample of 177 countries over the period 1960-2019 (1970-2017 in the case of financial crises). The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) a fter pandemic events; t=0 is the year of the pandemic event. Estimates based on  $y_{i,t+k}=\alpha_i^k+\gamma_t^k+\beta^kD_{i,t}+\theta^kM_{i,t}+\varepsilon_{i,t+k}$ .  $y_{i,t}$  is the Gini coefficient for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that a ffects country i in year t;  $C_{i,t}$  is a dummy variable denoting, a Iternatively, the year of occurrence of a financial crisis or a year of negative growth,  $M_{i,t}$  is a vector that includes two lags of the dependent variable and the pandemic dummy plus two lags of the financial crisis (recession). See Table A2-A3 in the Online Appendix for the full list of pandemic events. The F-tests for the difference between the estimations in the case of Pandemics and Financial Crises (Recessions) are shown in Table A7 in the Online Appendix.

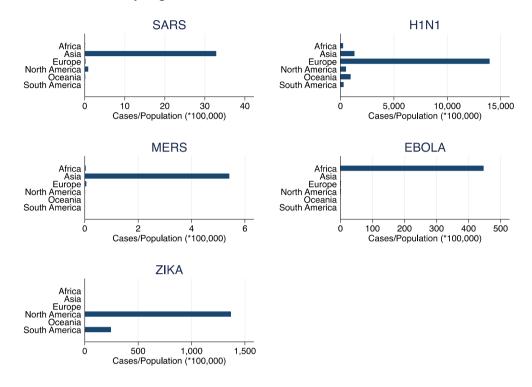

FIGURE 5. IMPACT OF PANDEMICS ON NET GINI—THE ROLE OF THE SEVERITY OF THE PANDEMIC

Notes: Impulse response functions are estimated using a sample of 177 countries over the period 1960-2019. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) after pandemic events; t=0 is the year of the pandemic event. For Panel A, estimates based on  $y_{i,t+k}=\alpha_i^k+\gamma_t^k+\beta^k \log(cases_{i,t})=+\theta^k X_{i,t}+\varepsilon_{i,t+k}$ , where  $\log(cases_{i,t})=\log_{10}\left(1+\frac{1000\cdot confirmed\_cases_{i,t}}{population_{i,t}}\right)$ . The instrumental variable (IV) a pproach consists of interacting an exogenous time-varying global term—the date of the initial pandemic outbreak in the world—and a country-specific terms exogenous to economic outcomes—such as a verage temperature (see Table A8 for first-stage estimate). For Panels B and C estimates based on  $y_{i,t+k}=\alpha_i^k+\gamma_t^k+F(z_{it})\left[\beta_L^k D_{i,t}+\theta_L^k X_{i,t}\right]+\left(1-F(z_{it})\right)\left[\beta_H^k D_{i,t}+\theta_H^k X_{i,t}\right]+\varepsilon_{i,t+k}$ .  $y_{i,t}$  is the Gini coefficient for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that affects country i in year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable and the pandemic dummy.  $F(z_{it})$  is an indicator function of the severity of the pandemic. The coefficients  $\beta_L^k$  and  $\beta_H^k$  capture the distributional impact of a pandemic event at each horizon k in cases of extremely severe pandemics ( $F(z_{it})\approx 1$  when z goes to minus infinity) and weak pandemics ( $1-F(z_{it})\approx 1$  when z goes to plus infinity), respectively. The F-tests for the difference between the estimations in the case of low and high regime of the interaction variable with the pandemic dummy are shown in Table A7 in the Online Appendix. See Table A2-A3 in the Online Appendix for the full list of pandemic events.

#### ANNEX A

Figure A1. Pandemic cases by regions

Sources: WHO, Ma and others (2020); ECDC, CDC; PAHO; Wikipedia. Information in the table refers to countries for which data on Net Gini are available (i.e. for Ebola not all countries affected by the epidemic event are included in our analysis due to data constraints). The sources of the number of cases/deaths are as follows (accessed on June 24, 2020). Data on Population are from the World Bank's World Development Indicator Database.

Figure A2. Impact of pandemics on market Gini

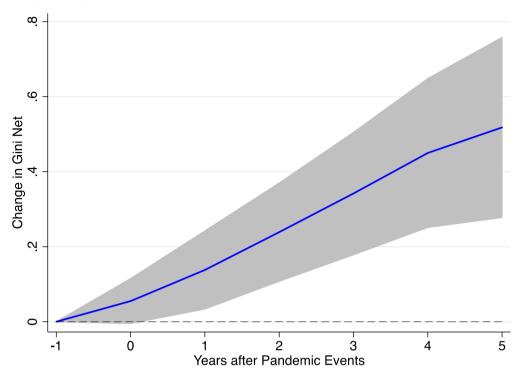

Notes: Impulse response functions are estimated using a sample of 177 countries over the period 1960-2019. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) a fter pandemic events; t=0 is the year of the pandemic event. Estimates based on  $y_{i,t+k} = \alpha_i^k + \gamma_t^k + \beta^k D_{i,t} + \theta^k X_{i,t} + \varepsilon_{i,t+k}$ .  $y_{i,t}$  is the Gini coefficient for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that a ffects country i in year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable and two lags of the pandemic dummy. See Table A2-A3 for the full list of pandemic events.

Figure A3. Impact of pandemics on net Gini—different measures of inequality

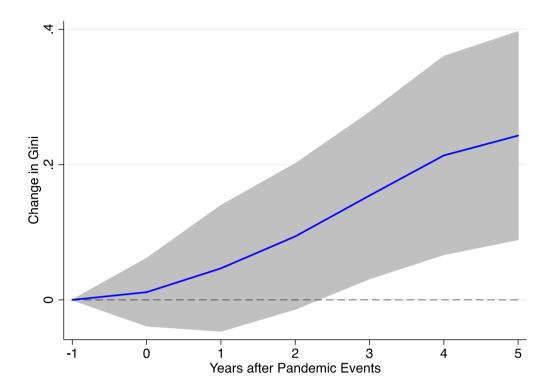

Notes: Impulse response functions are estimated using, a Iternatively, Gini POVCAL (69 countries – 763 observations) and Gini WIDER (66 countries – 641 observations). The graph shows the responses and 90 percent confidence bands. The x-axis shows years (k) a fter pandemic events; t=0 is the year of the pandemic event. Estimates based on  $y_{i,t+k}=\alpha_i^k+\gamma_t^k+\beta^kD_{i,t}+\theta^kX_{i,t}+\varepsilon_{i,t+k}$ .  $y_{i,t}$  is the Gini coefficient for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $\gamma_t$  is a dummy variable indicating a pandemic event that affects country  $\gamma_t$  in year  $\gamma_t$  in year  $\gamma_t$  is a vector that includes two lags of the dependent variable and two lags of the pandemic dummy.

Figure A4. Impact of pandemics on net Gini—ADL

Notes: Impulse response functions are estimated using a sample of 177 countries over the period 1960-2019. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) a fter pandemic events; t=0 is the year of the pandemic event. Estimates based on  $\Delta y_{i,t} = \alpha_i + \gamma_t + \beta_k(l)D_{i,t} + \varepsilon_{i,t}$ .  $y_{i,t}$  is the Gini coefficient for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that a ffects country i in year t. See Table A2-A3 for the full list of pandemic events.

Figure A5. Impact of pandemics on net Gini—Restricted sample (1995-2019)

Notes: Impulse response functions are estimated using a sample of 177 countries over the period 1995-2019. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) after pandemic events; t=0 is the year of the pandemic event. Estimates based on  $y_{i,t+k} = \alpha_i^k + \gamma_t^k + \beta^k D_{i,t} + \theta^k X_{i,t} + \varepsilon_{i,t+k}$ .  $y_{i,t}$  is the Gini coefficient for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that affects country i in year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable and two lags of the pandemic dummy. See Table A2-A3 for the full list of pandemic events.

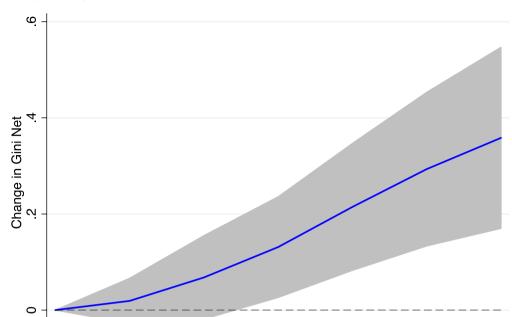

Figure A6. Impact of pandemics on net Gini—Additional controls

Ó

Notes: Impulse response functions are estimated using a sample of 175 countries over the period 1960-2017. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) after pandemic events; t=0 is the year of the pandemic event. Estimates based on  $y_{i,t+k} = \alpha_i^k + \gamma_t^k + \beta^k D_{i,t} + \theta^k X_{i,t} + \varepsilon_{i,t+k}$ .  $y_{i,t}$  is the Gini coefficient for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that affects country i in year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable, two lags of the pandemic dummy, the level of GDP, the level of GDP square, population density, the share of population in urban area, the KOF index of trade globalization and the KOF index of financial globalization. See Table A2-A3 for the full list of pandemic events.

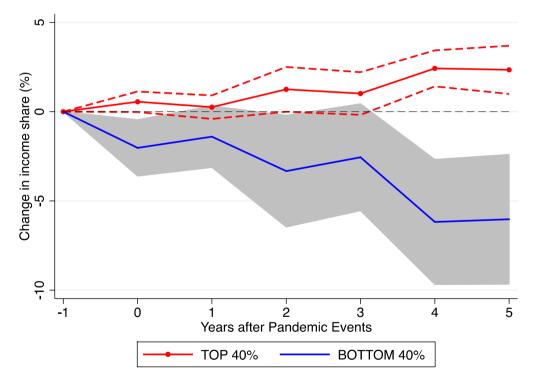

Figure A8. Impact of pandemics on net Gini—Placebo test

Notes: Impulse response functions are estimated using a sample of 177 countries over the period 1960-2019. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) a fter pandemic events; t=0 is the year of the pandemic event. Estimates based on  $y_{i,t+k} = \alpha_i^k + \gamma_t^k + \beta^k D_{i,t} + \theta^k X_{i,t} + \varepsilon_{i,t+k}$ .  $y_{i,t}$  is the Gini coefficient for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that a ffects country i in year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable and two lags of the pandemic dummy. The placebo test is conducted estimating the impulse responses attributing the values of our measure of the shock,  $D_{i,t}$ , randomly, a cross the whole sample.

Figure A9. Impact of pandemics on shares of income, by deciles – robustness checks

Notes: Impulse response functions are estimated using a sample of 64 countries over the period 1981-2017. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) a fter pandemic events; t=0 is the year of the pandemic event. Estimates are based on  $y_{i,t+k}-y_{i,t-1}=\alpha_i^k+\gamma_t^k+\beta^kD_{i,t}+\theta^kX_{i,t}+\varepsilon_{i,t+k}$ .  $y_{i,t}$  is, in turn, the log of the income share held by the top (bottom) 10% (40%) for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that affects country i in year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable and two lags of the pandemic dummy. See Table A2-A3 for the full list of pandemic events.

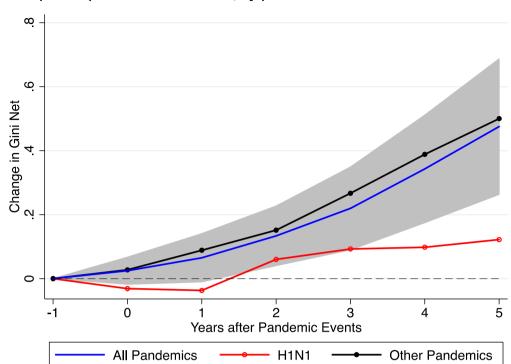

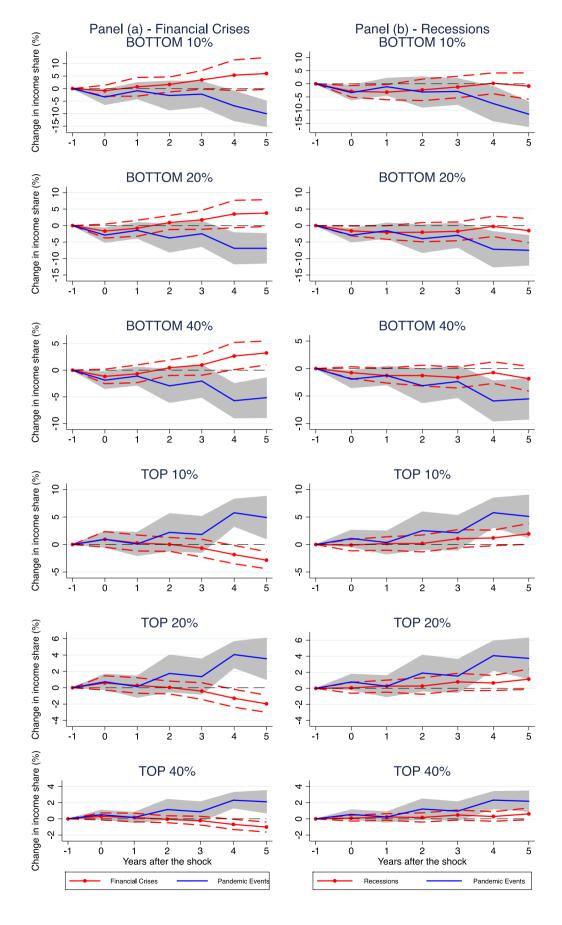

Figure A10. Impact of pandemics on net Gini, by pandemics – robustness checks

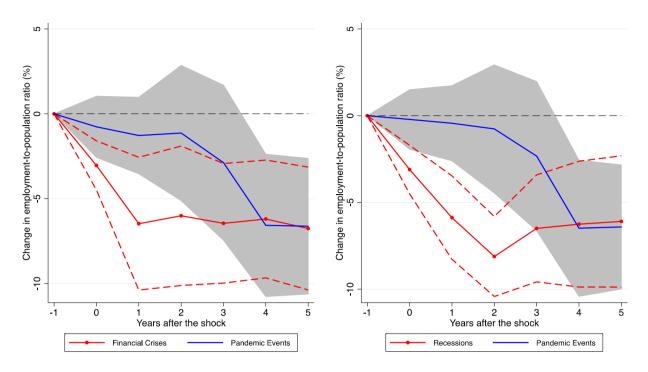

Notes: Impulse response functions are estimated using a sample of 177 countries over the period 1960-2019. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) after pandemic events; t=0 is the year of the pandemic event. Estimates based on  $y_{i,t+k} = \alpha_i^k + \gamma_t^k + \beta^k D_{i,t} + \theta^k X_{i,t} + \varepsilon_{i,t+k}$ .  $y_{i,t}$  is the Gini coefficient for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that a ffects country i in year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable and two lags of the pandemic dummy. See Table A2-A3 for the full list of pandemic events.

Figure A11. Impact of pandemics, financial crises and recessions on shares of income, by deciles

Notes: Impulse response functions are estimated using a sample of 64 countries over the period 1981-2017. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) a fter pandemic events (financial crises or recessions); t=0 is the year of the pandemic event (financial crisis or recession). Estimates based on  $y_{i,t+k}-y_{i,t+1}=\alpha_i^k+\gamma_t^k+\beta^kD_{i,t}+\vartheta^kC_{i,t}+\theta^kM_{i,t}+\varepsilon_{i,t+k},y_{i,t}$  is, in turn, the log of the income share held by the top (bottom) 10%, 20%, or 40% for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that a ffects country i in year t;  $C_{i,t}$  is a dummy variable denoting, alternatively, the year of occurrence of a financial crisis or a year of negative growth,  $M_{i,t}$  is a vector that includes two lags of the dependent variable, two lags of the pandemic dummy plus two lags of the financial crisis (recession). See Table A2-A3 for the full list of pandemic events.

Figure A12. Impact of pandemics, financial crises and recessions on E/P ratio – basic education

Notes: Impulse response functions are estimated using a sample of 76 countries over the period 1990-2017. The graph shows the response and 90 percent confidence bands. The x-axis shows years (k) a fter pandemic events (financial crises or recessions); t=0 is the year of the pandemic event (financial crisis or recession). Estimates based on  $y_{i,t+k}-y_{i,t+1}=\alpha_i^k+\gamma_t^k+\beta^kD_{i,t}+\vartheta^kC_{i,t}+\theta^kM_{i,t}+\varepsilon_{i,t+k}$ .  $y_{i,t}$  is, in turn, the log of employment-to-population ratio by education level for country i in year t;  $\alpha_i$  are country fixed effects;  $\gamma_t$  are time fixed effects;  $D_{i,t}$  is a dummy variable indicating a pandemic event that affects country i in year t;  $C_{i,t}$  is a dummy variable denoting, a Iternatively, the year of occurrence of a financial crisis or a year of negative growth,  $M_{i,t}$  is a vector that includes two lags of the dependent variable, two lags of the pandemic dummy plus two lags of the financial crisis (recession). See Table A2-A3 for the full list of pandemic events.

 Table A1. Data Sources and Descriptive Statistics

Variable	Source	Obs	Mean	Std. Dev.	No. of Countries
		5 450	45.20	ć <b>7</b> 0	155

Observations	3,298	3,298	3,213	3,094	2,971	2,849

Notes:. Empirical sandwich standard errors (clustered by country) in parentheses \*\*\* p<0.01, \*\* p<0.05, \* p<0.1. AIPW estimates based on the baseline model as in equation (1). Results for Panels A and B are based on the propensity scores obtained using the model of column 2 and 4 of Table A6, respectively. When imposing  $\theta_1^h = \theta_0^h$  (i) the effect of the controls  $X_t$  on the outcomes is assumed to be stable across the treated and control subpopulations (i.e. countries experiencing a pandemic event and countries not experiencing a pandemic event); (ii) the expected value of  $X_t$  in each subpopulation is assumed to be the same. When imposing  $\theta_1^h \neq \theta_0^h$  these assumptions are relaxed. For further details see the methodological section and Jordà and Taylor (2016).

#### **ANNEX B**

#### Augmented inverse probability weighting (AIPW) estimation

In order to further address endogeneity, we adapt the approach proposed by Jordà and Taylor (2016) to estimate the causal effect of austerity, and we use the Augmented Inverse Probability weighting (AIPW). The rationale of this approach is to address potential endogeneity in the measure of treatment (the pandemic event in our case). Indeed, pandemics may not be fully exogenous events and be related to pre-existing country characteristics. We therefore construct a predictive model for the likelihood of pandemics using various specifications including the level of GDP level its growth rate, average country temperature, total health expenditures, government final expenditures, mortality rate, and other controls. "The predictive model serves to reallocate probability mass from the regions of the distributions in the treatment/control subpopulations that are oversampled to those regions that are under-sampled, thus enabling identification in the framework of the Rubin Causal Model" (Jordà and Taylor, 2016). Table A5 reports the Probit regression results. As shown in the table, the dates of pandemic events are uncorrelated with past levels and changes of inequality, but depend on some country characteristics such as temperature and GDP per capita.

Since we are interested in estimating the Average Treatment Effect (ATE) we use an augmented regression-adjusted estimation instead, denoted AIPW, which combines IPW with regression control and adjusts the estimator to achieve semi-parametric efficiency. Specifically, we estimate the following model

$$y_{i,t+k} = \alpha_i^k + \gamma_t^k + \Lambda^k D_{i,t} + \theta^k X_{i,t} + \varepsilon_{i,t+k} \ (\text{A1})$$

with:

$$\begin{split} \widehat{\Lambda}_{AIPW}^{k} &= \frac{1}{n} \sum_{t} \left\{ \left[ \frac{D_{t}(y_{t+k})}{\hat{\mathbf{p}}_{t}} - \frac{(1-D_{t})(y_{t+k})}{(1-\hat{\mathbf{p}}_{t})} \right] \right. \\ &\left. - \frac{(D_{t} - \hat{\mathbf{p}}_{t})}{\hat{\mathbf{p}}_{t}(1-\hat{\mathbf{p}}_{t})} \left[ (1-\hat{\mathbf{p}}_{t}) m_{1}^{h} \big( X_{t}, \hat{\theta}_{1}^{h} \big) + \hat{\mathbf{p}}_{t} m_{0}^{h} \big( X_{t}, \hat{\theta}_{0}^{h} \big) \right] \right\} \end{split}$$

where:  $\hat{p}_t$  is the propensity score obtained from estimating the Probit models as in Table A5;  $m_j^h(X_t, \hat{\theta}_j^h)$  for j=1,0 is the conditional mean from the first-step regression of  $(y_{i,t+k})$  on  $X_t$ ;  $\hat{\theta}_j^h$  is the parameter accounting for the differential effect of the treatment conditioned to the value of the  $X_t$ ;  $y_{i,t}$  is our distribution variable (e.g. the Gini coefficient) for country i in year t;  $\alpha_i$  are country fixed effects, included to take account of differences in countries' average income distribution;  $\gamma_t$  are time fixed effects, included to take account of global shocks such as shifts in oil prices or the global business cycle;  $D_{i,t}$  is a dummy variable indicating a pandemic event that

affects country i in year t.  $X_{i,t}$  is a vector that includes two lags of the dependent variable and two lags of the pandemic dummy. The results are reported in Table A6. Regardless of the specification chosen, they point to statistically significant impact of pandemics on income inequality with effects being quantitatively close to those shown in Figure 1.

# Alternative identification strategy and IV approach

We alternatively estimate the effects of pandemics on inequality using the number of infections instead of the pandemic dummy as the main dependent variable. In particular, we consider the logarithm of base 10 of the number of confirmed cases per 1000 inhabitants in each country (we add 1 so that the new variable takes on zero years without pandemics):  $log_{10} \left(1 + \frac{1000 \cdot confirmed\_cases_{i,t}}{population_{i,t}}\right)$ .

While the use of this continuous variable has the main advantage to differentiate episodes based on their severity, it has also two important drawbacks compared to the dummy variable. First, it may more prone to reverse causality as higher initial levels of inequality may increase the number of infections due to the higher economic and health vulnerability of marginalized people. Second, measurement errors related to the total cases detected is likely to be non-negligible.

To address these concerns, we resort to an instrumental variable approach. Following Nunn and Quian (2014), our Instrumental Variable (IV) approach consists of interacting a time-varying global term and a constant country-specific term. The global term we consider is a dummy variable that takes the value of 1 for all countries in the years of pandemic outbreaks. The country-term we consider captures a key factor affecting the severity of the pandemic. For this purpose, we consider the average temperature. As shown in several recent studies (i.e. Ma et al, 2020b; Ujiie et al. 2020), this factor is an important driver of the evolution of pandemics and it can reasonably be assumed to be exogenous. Our IV estimation reads as follows:

$$y_{i,t+k} = \beta_c^k \log(\widehat{case}s_{i,t}) = +\theta^k X_{i,t} + \alpha_i^k + \gamma_t^k + \epsilon_{i,t}^k$$
 (A2) with 
$$\log(\widehat{case}s_{i,t}) = \vartheta^k S_{i,t} + \varphi^k X_{i,t} + \alpha_i^k + \gamma_t^k + v_{i,t}^k,$$

where S is the instrument. The analysis also controls for country and time fixed effects and can therefore be seen as a *differences-in-differences* approach (Nunn and Quian 2014).

The first-stage estimates suggest that the instrument is "strong" and statistically significant. The Kleibergen-Paap rk Wald F-statistic—which is equivalent to the F-effective statistic for non-homoscedastic error in case of one endogenous variable and one instrument (Andrews et al., 2019)—is higher than the associated Stock-Yogo critical value (Table A8).
