

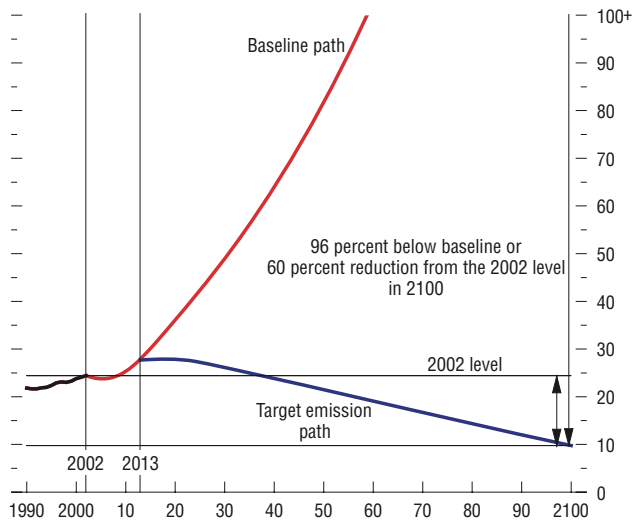

Figure 4.9. Global Emission Targets and Paths, 1990–2100

(Gigatons of carbon dioxide)

The baseline path shows the projected level of global energy-based emissions under the assumption of a no-mitigation policy. The target emission path shows the level of global emissions from fossil fuels achieved in the policy simulation results, reaching a level that is 60 percent below the level of global emissions in 2002. The target level in 2100 is 96 percent below the projected level of the baseline in 2100.
