The narrowing of current account imbalances since 2006 is likely to be long lasting, as cyclical factors appear to have played a relatively minor role. Even in the worst-case scenario, which results from estimating output gaps as the difference between the actual level of output in 2013 and the 2013 level extrapolated using precrisis trends, the current account narrowing amounts to around 1 ½ percent of world GDP (which is almost half the adjustment without cyclical factors).
