March 2004

Abstract

This Working Paper should not be reported as representing the views of the IMF.

The views expressed in this Working Paper are those of the author(s) and do not necessarily represent those of the IMF or IMF policy. Working Papers describe research in progress by the author(s) and are published to elicit comments and to further debate.

This study discusses the role of domestic debt markets in sub-Saharan Africa (SSA) based on a new dataset covering 27 SSA countries during the 20-year period 1980–2000. The study finds that domestic debt markets in these countries are generally small, highly short-term in nature, and often have a narrow investor base. Domestic interest payments present a significant burden to the budget, despite much smaller domestic than foreign indebtedness. The use of domestic debt is also found to have significantly crowded out private sector lending. Finally, the study identifies significant differences between the size, cost, and maturity structure of domestic debt markets in HIPCs and non-HIPCs.

I. Introduction

In the past decades, the external debt burden and its impact on fiscal sustainability and economic growth in low-income countries have been extensively debated. This debate has culminated in various debt reduction plans, such as the recent Heavily Indebted Poor Countries (HIPC) Initiative, which have sought to reduce the external debt stocks in these countries and free up resources for pro-growth government spending. However, at least until recently, much less attention has been given to the issue of domestic debt in low-income countries, despite its potential significant impact on government budgets, macroeconomic stability, private sector lending, and ultimately growth performance. Existing studies have, so far, been limited mostly to individual country assessments in the context of Financial Sector Assessment Programs (FSAP) or theoretical analyses of domestic debt. Moreover, data on domestic debt are scarce and limited to a few African countries.

The main objective of this study is to discuss the long-term developments and identify key characteristics of African domestic debt markets based on a newly collected database for 27 non-CFA sub-Saharan African (SSA) countries covering 1980–2000. The discussion will focus on the following issues: (i) the development in domestic debt markets over the period relative to various indicators; such as GDP, foreign debt, and broad money; (ii) the investor base of the debt markets, especially the degree to which the bank and nonbank sectors hold domestic debt; (iii) the development in real treasury bill interest rates in view of the significant financial sector reforms that have taken place over the period; (iv) the maturity structure of the domestic debt portfolio in these countries, including a comparison with debt markets in more developed countries; and (v) the impact of domestic borrowing on government budgets and private sector credit.

Of particular interest is the difference between domestic debt markets in HIPCs and non-HIPCs. First, the paper examines to what extent HIPCs have relied on foreign versus domestic debt. Given that HIPCs have access to highly concessional foreign resources, it would be surprising if they have accumulated significant amount of domestic debt, since domestic interest rates are higher than foreign ones. Finally, the relatively underdeveloped financial systems in many HIPCs may have been an obstacle to developing sound and well-functioning domestic debt markets compared with those of non-HIPCs.

II. DESCRIPTION OF DATABASE

This study is the first attempt to compile a comprehensive database on domestic debt for sub-Saharan African countries. While other databases exist, these are scarce and limited only to a few African countries. The most comprehensive database to date is the government financial statistics in the IMF's *International Financial Statistics*. However, it only contains data for 19 out of 38 non-CFA countries, and the data for many of these countries are incomplete. Another source is the World Bank's *World Development Indicators*, but the problem of missing data is even larger in this case.

The database for this study contains information about the characteristics of domestic debt markets for the period 1980–2000. The study focuses on gross securitized domestic government debt, comprising treasury bills, development stocks, and bonds. Hence, the dataset excludes domestic debt arising from domestic arrears accumulation and direct advances from the central bank and commercial banks. While an attempt was made to collect outstanding stocks of central bank debt (since it represents a quasi-fiscal cost to the government), it was not possible to obtain information for all countries. In addition to the stock of domestic debt, the database also contains information on the maturity structure, holdings of debt by sectors, real treasury bill interest rates, and the domestic interest burden to the budget.

The choice of countries was limited to non-CFA countries, since CFA countries until very recently did not have any domestic debt markets. Among the non-CFA countries, Angola, Botswana, the Democratic Republic of the Congo, Mozambique, and São Tomé and Príncipe did not have domestic government debt markets at the time of collection. Apart from these countries, it was possible to obtain complete series for all countries except Guinea. Information on domestic debt data was obtained primarily from individual IMF country reports, such as recent economic development reports and country desk databases. In cases where these were insufficient, central bank reports or IMF country desk economists helped to fill the gaps.

III. IMPORTANT ASPECTS OF DOMESTIC DEBT MANAGEMENT

The need for domestic debt issuance

The need to issue domestic debt can arise both from government deficits that are not fully foreign financed and implementation of monetary policy. Generally, the deficit leads to a change in government net assets. Hence, a budget deficit can be financed either by drawing down assets or incurring new liabilities of both domestic and foreign nature. The use of assets entails selling property or reducing deposits. This type of financing is, however, constrained by the stock and attractiveness of assets (the feasibility of privatization), and governments, therefore, normally resort to domestic or foreign borrowing to finance large parts of the fiscal deficits. The choice between foreign and domestic borrowing, in turn, depends on the cost (interest rates), maturity structure, and risks. Most of the SSA countries have access to foreign financing at very low interest rates (well below market interest rates) and at very long maturity from international aid agencies or on grant terms. These terms are often more favorable than for domestic borrowing, as domestic debt instruments carry much

_

² Most countries do not have significant stocks of direct advances as governments as governments generally clear these at the end of the year through issuance of treasury bills or transfers from other government accounts. However, a few number of the countries in the database have accumulated significant stocks of direct liabilities to the banking system.

higher interest rates and have shorter maturities. Another advantage of foreign borrowing is that it increases the supply of foreign exchange, which is critical to meet import requirements. One drawback concerning foreign borrowing is the currency risk, which may increase along with the foreign indebtedness, given that a growing foreign debt service increases the demand for foreign exchange. However, Beaugrand, Loko, and Mlachila (2002) found that highly concessional foreign loans—when available—are still the most attractive way to finance budget deficits even realizing significant devaluation risks, given the high levels of domestic interest rates.

Despite the attractiveness of foreign borrowing, governments may still look toward domestic borrowing for a number of reasons. First, the supply of foreign (concessional) financing may be determined by the aid agencies' budget and their assessment of the economic performance in the recipient country. Second, international aid is very often linked to project financing and can therefore not finance government's recurrent expenditures or capital projects not supported by donors. Hence, governments with large recurrent budget deficits may be forced to tap into domestic savings, including through issuance of domestic debt, to close their budget gaps.

Domestic debt can also be used to achieve monetary policy targets. This is particularly the case in countries with large balance of payments surpluses, created by large aid inflows or oil exports, for example. In those situations, the inflows of foreign exchange increases liquidity which could undermine macroeconomic stability and the central banks often decide to intervene by selling government or central bank bills to stem inflationary pressures from excess liquidity.

Macroeconomic risks related to domestic debt financing

Extensive use of domestic borrowing can have severe repercussions on the economy. Domestic debt service can consume a significant part of government revenues, especially given that domestic interest rates are higher than foreign ones. The interest cost of domestic borrowing can rise quickly along with increases in the outstanding stock of debt, especially in shallow financial markets. In such markets, given that financial resources are limited, expansions in domestic debt will more easily lead to higher domestic interest rates. The increase in interest rates may be even more pronounced if the investor base is relatively narrow, as the government may be held hostage by a particular group of investors (World Bank and IMF, 2001). A diverse investor base reduces the monopoly power of a particular group of investors, bringing down not only costs but also roll-over risks. Hence, an important aspect of debt management is to broaden the investor base. This can be achieved through a combination of efforts, including promoting investment by retail investors and development and reform of pension and retirement funds to encourage their investment in government bonds.

Another risk concerns the crowding out of private investment. When issuing domestic debt, governments tap into domestic private savings that would otherwise have been available to the private sector. This is normally followed by an increase in domestic interest rates if these are flexible, adversely affecting private investment. However, even where interest rates are controlled, domestic borrowing can lead to credit rationing and crowding out of private sector investment (Easterly and Fischer, 1990). The impact of government borrowing will, to some extent, be aggravated if there are capital account restrictions, since banks cannot as easily circumvent higher domestic interest rates through foreign borrowing. Last, but not least, an investor base that is dominated by commercial banks may exacerbate the abovementioned effect. The crowding out effect may, therefore, be more pronounced in the absence of nonbank investors, such as pension funds and retirement funds, to which the government could sell its debt without necessarily crowding out private sector credit. Hence, a diverse investor base prevents excessive reliance on commercial bank funds and thereby reduces the risk of crowding out (World Bank and IMF, 2001).

Maturity structure

The government debt portfolio should adequately comprise short- and long-term paper. If the debt portfolio mainly consists of short-term debt, the government may face considerable risks. First, with more frequent roll-overs, the government is highly vulnerable to a sudden increase in interest rates, which can raise the debt service significantly. This could lead to further deterioration in the market's confidence in government bonds, prompting even higher interest rates on government debt. Second, administrative costs tend to be higher with a short maturity structure, as the government must frequently roll over large parts of its debt, notably in countries without an automated book-entry system. Third, the maturity structure is important for the investors as they seek to diversify their asset portfolios. In many African countries, government debt is the only investment opportunity besides lending to the private sector since stock markets are either absent or highly illiquid (Gelbard and Leite, 1999). The provision of government longer-term paper is therefore highly important for investors to balance their long-term liabilities with long-term assets and for banks to increase profitability by taking on interest rate risk.

However, the government may experience several obstacles in pursuing a longer-term debt portfolio. First, the market may not be willing to hold long-term paper in view of significant inflation and default risks. Second, it may not be sufficiently advanced to demand long-term paper, especially in the absence of institutional investors (Impavido, Musalem, and Tressel, 2003). Finally, the government itself may hesitate to extend the maturity, since longer-term bonds can entail higher interest rates, in view of a positively sloped yield curve, which would increase financing cost.

IV. CHARACTERISTICS OF DOMESTIC DEBT MARKETS IN NON-CFA SSA COUNTRIES

A. Developments in Domestic Debt: 1980–2000

Table 1 shows the developments in domestic and external debt for 27 non-CFA SSA countries for the period 1980–2000. It is apparent that domestic debt is not a recent phenomenon in African countries as most of the countries have relied on domestic borrowing since the beginning of the observation period. However, the average ratio of domestic debt has increased from 11 percent of GDP in the 1980s to 15 percent in the late 1990s, with the median increasing from 4 percent to 10 percent over the same period. An increasing number of countries became heavily, domestically indebted, and the number of countries with debt-to-GDP ratios exceeding 20 percent rose from three at the beginning of 1980 to nine by 2000.

There are wide differences across the countries with respect to the size of government securities markets. One group of countries has relied extensively on domestic debt since the beginning of period. This group includes Ethiopia, Kenya, Mauritius, Nigeria, South Africa, Tanzania, Zambia, and Zimbabwe. In contrast, countries such as Angola, Botswana, the Democratic Republic of the Congo, Mozambique, and São Tomé and Príncipe, have not used or have only recently developed government securities markets. Between these extremes, there is a vast group of countries that have either fairly small debt markets, or have recently experienced a considerable increase in their domestic debt burden, including The Gambia, Ghana, Seychelles, and Namibia.

In addition, Table 1 reveals that the domestic debt burden in HIPCs is much smaller than in non-HIPCs. HIPCs, which almost by definition, have relied heavily on foreign financing, have not developed their domestic debt markets to the same degree as non-HIPCs. On average, domestic debt in HIPCs amounted to about 8 percent of GDP, although this ratio increased slightly in the latter half of the 1990s, mostly because of large increases in outstanding domestic debt in Ghana and The Gambia. However, other HIPCs have managed to obtain significant reductions in the ratio of domestic debt to GDP over the same period, notably Ethiopia and Zambia. In contrast, domestic debt markets have steadily grown in non-HIPCs as the average ratio of domestic debt to GDP has increased from 14 percent in the 1980s to 23 percent by end-1990s.

_

³ Mozambique and Botswana have fairly developed markets for central bank notes.

Finally, Table 1 shows that while domestic debt stocks have grown in recent years relative to GDP, their size is still negligible compared with the size of foreign indebtedness. Domestic debt only accounted for just over a fifth of total debt in the latter half of the 1990s, slightly lower than in the 1980s. However, there are marked differences between HIPCs and non-HIPCs. While domestic debt financing has grown relatively to foreign borrowing in non-HIPCs, domestic borrowing in HIPCs has been dominated by the huge accumulation of external debt in the 1990s. As a result, the ratio of domestic debt to total debt between the two groups diverged significantly in the 1990s from relatively similar levels in the 1980s as the ratio of domestic debt fell to less than 10 percent of total debt in HIPCs while it increased to almost 40 percent in non-HIPCs by the end of the 1990s.

As mentioned in Section III, the scope for expanding domestic debt depends on the depth of the financial sector. A useful indicator in that regard is the ratio of broad money to GDP. Table 2 shows that African financial sectors generally appear to be relatively small and on average, they tend to be much smaller in HIPCs than in non-HIPCs. The "deepest" financial sectors were found in Cape Verde, Kenya, Mauritius, Seychelles, and South Africa, where broad money amounted to more than 50 percent of GDP in the late 1990s.

The small financial sectors in most countries limit the scope for expanding domestic debt. The ratio of domestic debt to broad money is shown in Table 2. A number of countries had very large ratios of domestic debt to broad money at the end of 1990s, including The Gambia, Ghana, Nigeria, Seychelles, South Africa, and Zimbabwe. The ratio for Ghana was even larger than 100 percent. Interestingly, the average ratio is almost the same in HIPCs as in non-HIPCs despite the fact that the former group has much less domestic debt. In other words, the scope for expanding domestic debt in HIPCs appears to be more limited, particularly in The Gambia, Ghana, Malawi, Sierra Leone, and Tanzania, compared with non-HIPCs as further expansions of domestic debt in HIPCs would increase the scarcity of commercial bank resources and, thereby, curb credit to the private sector.

B. The Investor Base

As mentioned above, a diverse investor base is crucial to lowering the cost of government debt and the volatility of market yields. Furthermore, a narrow investor base, mainly consisting of commercial banks, increases the risk of crowding out private investment, especially in SSA countries where private companies have to rely on bank financing given the absence of corporate debt markets. As such, an important component of debt management is to stimulate a diverse investor base and develop instruments, trading

facilities, and distribution networks that best suit the needs of investors (World Bank and IMF, 2001). In most developed market economies, there are traditionally four general categories of potential investors in government securities instruments: domestic and foreign and, for each of these categories, the banking sector (comprising commercial banks as well as central banks) and the nonbank sector consisting of contractual savings sector (pension funds), collective investment funds, and nonfinancial entities such as nonfinancial corporations and individual investors. The presence of foreign investors in African securities markets is generally limited. To date, only a few countries had active participation of foreign

investors in their debt markets, which may be a result of underdeveloped trading facilities, high country risk, and capital account restrictions.

Commercial banks are the main holders of government debt in the African debt market, holding half of all outstanding domestic debt (Table 3). While they enjoy a relatively high income from government debt, their large holdings of domestic debt may also reflect some fundamental shortcomings in their commercial banking operations (World Bank and IMF, 2001). These shortcomings include institutional weaknesses that undermine lending to the private sector given ineffective screening and monitoring capabilities of loans, a small amount of reliable information on creditworthy borrowers, and weak legal systems (such as the absence of commercial courts to settle payments disputes).⁴

The nonbank sector was found to be the second biggest holder, accounting for a third of outstanding debt. The limited role played by the nonbank sector compared with commercial banks may be the absence of large-scale institutional investors in the nonbank sector. However, the nonbank sector was found to play an important role in Kenya, Madagascar, Mauritius, Rwanda, and South Africa. Insurance companies and pension funds were in these cases the most common investors, but building societies, post office savings banks, public enterprises, and the general public also played a role.

Finally, central banks accounted for a modest share of government debt, with the exception of Burundi, Nigeria, and Tanzania. While such holdings can be utilized for monetary policy purposes, central bank purchases of government debt are basically identical to monetizing budget deficits.

C. Real Treasury Bill Rates and Financial Sector Reforms

Financial systems in most African countries were highly controlled in the 1980s. However, many countries embarked on a series of financial sector reforms in the late 1980s aimed at liberalizing their financial sectors to improve financial intermediation. In many cases, these reforms included a move toward more liberal government debt markets based on flexible and market-determined interest rates, subject to the level of inflation, the outstanding amount of

⁴ A good measure of these shortcomings is the amount of nonperforming loans (NPL). Mehran and others (1998) found that the ratio of NPL to total loans averaged 16 percent in 16 non-CFA countries. The ratio was significantly higher for HIPCs than in non-HIPCs with almost a quarter of total loans being recorded as NPLs in the former group.

debt, and the risk of default. This replaced a system in which the government often had forced the state-controlled financial system to hold government debt despite minimal returns. Whereas real interest rates on bonds were often negative in the pre-reform period, in the early 1990s they needed to increase to more positive realms in order to make bonds attractive.

The positive impact of these reforms on financial development and liberalization are evident from the index numbers in the first two columns of Table 4. These numbers are drawn from Gelbard and Leite (1999) and comprise six subcategories, each based on additional subindicators: (i) market structure; (ii) financial products; (iii) financial liberalization; (iv) institutional environment; (v) financial openness; and (vi) monetary policy instruments. A higher index number indicates a more developed financial system. It can be seen that the financial systems improved in virtually all countries, with the largest improvements observed in HIPCs (although they came from the lowest base).

Sources: IFS; and Gelbard and Leite (1999).

The liberalization of the financial system appears to have been accompanied by a sharp rise in real interest rates (Table 4). At the end of the 1990s, all countries had positive real treasury bill rates except for Madagascar, Malawi, Nigeria, and Sierra Leone. In comparison, 13 of 15 countries for which data were available had negative real treasury bill rates during the 1980s. In contrast, real treasury-bill rates in The Gambia and Kenya exceeded 10 percent at the end of the 1990s. As noted above, financial sectors in HIPCs developed more rapidly than in non-HIPCs, and this may also explain that they witnessed the largest increase in real treasury-bill rates from an average of -32 percent in the 1980s to 4 percent by the end of the 1990s. In contrast, securities markets in non-HIPCs were already relatively liberal in the 1980s, and only small increases were needed to achieve positive real treasury bill rates.

D. Maturity Structure

The maturity structure of government debt can affect both, the costs and risks of using domestic debt instruments. In general, the government should attempt to issue debt with appropriate maturity length that mirrors the maturity structure of the short-term current and long-term capital expenditures. However, the government may be tempted to issue mainly short-term debt if the yield curve is sufficiently upward sloping. Furthermore, while there are obvious benefits from extending the maturity structure, including a reduction in market and

rollover risks, the market may not be "ready" to absorb long-term paper, especially if there is considerable macroeconomic instability. In addition, the absence of a contractual savings sector and mutual funds with sufficiently long investment horizons may also limit the ability of the government to extend the maturity structure. To some extent, the length of the maturity structure can be viewed as a measure of the degree of market development.

Short-term paper dominates debt markets in Africa (Figure 1). Three-month bills are the most frequently used, accounting for almost 50 percent of outstanding debt stocks (implying that African governments, on average, must roll over half of their debt portfolio four times a year). The second most common maturity is 12 months, accounting for about a fifth of the bonds, while a tenth of all bonds have a six-month maturity.

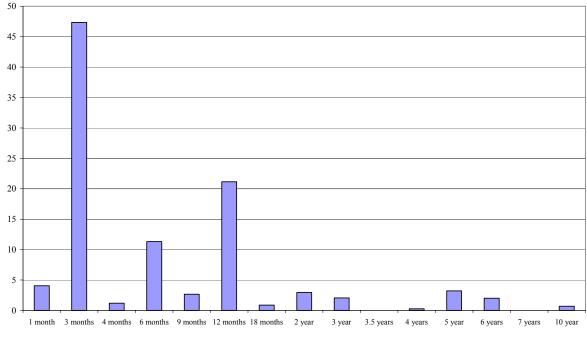

Figure 1. Average Maturity Structure of Domestic Debt in 14 Non-CFA SSA Countries

Source: Author's calculations.

The average maturity for the African countries is 231 days or about 10 months (Table 5). Domestic debt markets in HIPCs appear to have the shortest maturity structure of only 177 days. Burundi has the shortest average maturity of 77 days, closely followed by Uganda with 93 days. In contrast, non-HIPCs benefiting from more sophisticated markets have longer maturities; South Africa and Swaziland top the list with an average maturity length of 1,748 and 1,145 days, respectively.

As mentioned above, the dominance of short-term paper in African securities markets greatly increases rollover and market risks, especially in countries with large outstanding debt stocks. Financial liberalization has induced more interest rate flexibility and made countries

with large amount of short-term debt vulnerable to changes in market conditions. Some governments must rollover debt, amounting to a quarter of GDP, three or four times a year (on average).

^{1/} Data for 2000.

^{2/} GDP per capita (at constant 1995 U.S. dollar) in 2000.

The short-term nature of African debt markets is even more significant when compared with the debt markets in more developed countries. In six developed and emerging market countries for which data were available, the average maturity length was about five and half years or seven times longer than in African countries. Roughly speaking, the maturity length seems to be more closely related to general economic development (in terms of per capita income) than to the size of debt markets (relative to GDP). As a country gains wealth (with the exception of India) and the demand for more sophisticated economic arrangement expands, the need for longer-term savings instruments increases accordingly. This implies that as African countries continue to develop, their debt markets may be expected to become more advanced and long term in nature. This would help reduce the significant risks of portfolios dominated by short-term debt. A word of caution may be necessary in that some fairly poor countries have expanded their debt markets significantly in relatively undeveloped financial market settings—thereby ending up with sizable amounts of short-term debt causing a significant burden on, and risk to, the budget.

V. THE IMPACT OF DOMESTIC DEBT ON THE BUDGET AND PRIVATE SECTOR CREDIT

A. Budget Implications

A key concern regarding domestic debt management is the cost, in terms of amortization and interest payments, to the budget. This section will focus on interest, since most African governments have been net borrowers in domestic markets, rolling over existing debt. Two issues deserve attention: (i) the interest burden to the budget; and (ii) the relative cost of domestic versus foreign borrowing.

Domestic interest payments are sizeable compared with revenues and GDP (Table 6). Average interest payments, as a percent of revenues, have increased in both HIPCs and non-HIPCs over 1980–2000. However, large variations occur among the countries—Ethiopia, Lesotho, Madagascar, Nigeria, and Rwanda have all cut their interest payments significantly, as their debt stocks have fallen. In contrast, The Gambia, Ghana, Malawi, Sierra Leone, and Zimbabwe have witnessed a sharp increase in domestic interest payments to more than 15 percent of their revenues. Relative to GDP, domestic interest payments, on average, account for more than 2 percent of GDP in these countries. The ratio is slightly higher in non-HIPCs than in HIPCs.

Surprisingly, domestic interest payments are as large as foreign ones, despite much lower levels of domestic than foreign debt. In fact, domestic interest payments exceeded foreign interest payments in 10 (half of which were HIPCs) of the 22 countries for which data were available. Despite the drastic decline in domestic to total debt ratio in HIPCs, domestic interest payments in percent of total interest payments have remained relatively constant at about 40 percent throughout the period. Furthermore, domestic interest payments in HIPCs account for almost the same share of total interest payments as in non-HIPCs, despite much smaller domestic debt relative to foreign debt in HIPCs. Hence, in addition to the large

Table 6. Domestic Interest Payments 1980-2000.

foreign interest burden, recently highlighted by the HIPC Initiative, African governments have to pay a significant part of their revenues to service domestic debt.

The significant domestic interest burden is a result of relative high domestic interest rates. Various comparisons of the cost of domestic versus foreign borrowing suggest that domestic interest rates are much higher than foreign ones (Table 7). In order to measure the cost of

⁵ A more common approach is to look at the uncovered interest rate parity. However, using foreign market interest rates for African countries may overstate the cost, since most of their borrowing is on highly concessional terms with interest rates well below market rates. The implicit interest rate calculates the average interest rate, which takes into account the (expost) exchange rate depreciation.

end of the 1990s, the implicit domestic interest rate was found to average about 18 percent compared with 2 percent for foreign borrowing. At the same time, implicit domestic borrowing costs were found to be higher in HIPCs than in non-HIPCs. Implicit domestic interest rates are similar to the nominal treasury-bill rates.

A key question is what makes a government borrow domestically when the interest rates are much higher. First of all, amortization on external borrowings requires foreign exchange. Hence, the external vulnerability may increase dramatically if external indebtedness rises significantly. In contrast, the authorities can, at least in the short-run, rollover domestic debt without major macroeconomic implications. Second, in order to limit external vulnerability, many Fund-supported programs in poor countries include a cap on nonconcessional borrowing. Thus, if the governments in these countries cannot obtain sufficient concessional foreign assistance to meet their financing requirements, they must resort to relatively expensive domestic borrowing rather than filling the financing gap by more favorable nonconcessional foreign borrowing.

B. Impact on Private Sector Credit

As mentioned above, domestic debt can crowd out private sector credit with adverse consequences for private investment. In order to examine this effect, a simple panel data model was estimated, regressing private sector lending on domestic debt (both variables were in percent of broad money) for the 27 countries over the period 1980–2000. The results from this regression (shown in table below) found significant support for the crowding out hypothesis; on average across countries, an expansion in domestic debt of 1 percent relative to broad money causes the ratio of lending to the private sector to broad money to decline by 0.15 percent.

Table: regression results

	Domest	tc debt	Cons	tant	Obs	R ²
	c o e f	std. error	coef	std. error		
Private sector credit	-0.15	(0.03)	52.7	(1.54)	492	0.0007

Note: both variables in percent of M₂

The Gambia showed one of the strongest decreases in the ratio of private sector lending to broad money, dropping from about three-quarters to about one-third during the 20-year period from 1980 to 2000. This coincided with a strong expansion in domestic borrowing as the ratio of domestic debt to broad money rose to 106 percent by the end of the 1990s from an average of 13 percent in the 1980s. Another interesting case is Malawi, which also witnessed a sharp reduction in private sector lending in the latter half of the 1990s. Despite having a relatively small ratio of domestic debt to GDP, domestic debt assumed a relatively large proportion of broad money given the relatively underdeveloped financial sector (see Table 4). One exception is South Africa where the ratio of credit to the private sector increased despite expansion in domestic debt. This can be attributed to the small commercial bank holdings of government debt, which helped reduce the negative impact of debt expansion on private sector lending.

VI. CONCLUSION, POLICY IMPLICATIONS, AND NEEDS FOR REFORMS

This study has examined different features of domestic debt markets in non-CFA sub-Saharan African countries. Overall, the use of domestic debt instruments is not a recent phenomenon, since 18 out of 27 countries had domestic debt markets in 1980, a number that increased to 21 by the year 2000. The ratio of domestic debt increased from 11 percent in the 1980s to 15 percent of GDP by the end of the 1990s. However, the domestic debt burden is still small compared to the foreign indebtedness.

Even though the ratio of domestic debt to GDP is modest, domestic borrowing still assumes a large part of financial resources, given the thin and shallow financial markets in the countries. The ratio of domestic debt to broad money has been constant at about 40 percent throughout the period, but with some countries observing ratios of almost 100 percent. Since commercial banks hold more than half of the outstanding domestic debt, expansion in domestic debt has had a significant negative impact on private sector lending. The nonbank sector plays a limited role, given a relatively underdeveloped institutional investment sector in many of the countries. In addition, domestic markets were mainly of a short-term nature with the most common maturity being three months; the average maturity for fifteen SSA countries for which data were available was only 231 days, far shorter than in selected emerging market countries.

Domestic debt financing was found to be much more expensive than foreign borrowing. This may be explained by the ongoing financial liberalization, which has resulted in sharply rising real treasury bill rates, but also the fact that most countries borrow externally on highly concessional terms. Consequently, domestic interest payments present the same burden to the budget as the foreign debt does, even though the domestic debt burden comprises only a fraction of the total debt burden. While domestic interest payments, on average, assumed about one-tenth of total revenue, some countries, such as The Gambia, Ghana, Kenya, and Malawi, Seychelles, Sierra Leone, South Africa, and Zimbabwe have to set aside more than 15 percent of their revenues to pay interest on domestic debt.

The study also identified marked differences in the size, cost, and maturity of domestic debt markets between HIPCs and non-HIPCs. Given the significant reliance on external financing, HIPCs have accumulated less domestic debt, although some face a significant domestic debt burden in addition to their large stock of foreign debt. Despite the lower domestic debt to GDP, HIPCs have almost a similar ratio of domestic debt to broad money given the smaller degree of financial intermediation than in non-HIPCs. Thus further expansions in domestic debt are more likely to crowd out private investments in HIPCs. While HIPCs have embarked on comprehensive financial liberalization in the first part of the 1990s, real interest rates have surged considerably as a result. This, combined with a high degree of concessional foreign borrowing, explain the fact that domestic interest payments almost equal foreign ones in these countries, despite smaller amounts of domestic debt. Further, governments in HIPCs

face a much higher market risks as a result of the shorter maturity structure of domestic debt than in non-HIPCs.

The significant debt problems in many countries, both domestic and foreign, raise considerable concern about fiscal sustainability. In the worst case, this may call for reforms. One option would be to pursue debt reduction schemes for domestic debt similar to the HIPC Initiative. However, an outright reduction in domestic debt would increase the liquidity in the system and thereby endanger macroeconomic stability. Instead, one could consider a debt reduction scheme as in Cape Verde whereby a donor-financed trust fund was established. The foreign exchange from this fund was then utilized to retire domestic debt without injecting liquidity into the system because the foreign exchange transaction essentially absorbed the liquidity.

Another consideration is that countries could benefit from extending the maturity structure of domestic debt since Africa's debt markets tend to be of an extremely short duration. While this may entail greater debt-service costs to governments since bonds with longer terms may carry a higher interest rate, it would lower the significant market and rollover risks that they currently face. Given the nascent capital markets, such reforms should be accompanied by broader reforms seeking to increase demand for long-term paper, including strengthening and expanding the insurance and pension sector and strengthening corporate governance and institutions.

Finally, domestic debt markets would greatly benefit from improved foreign access to holdings of domestic debt. In addition to strengthening competition, which would reduce financing costs, a strong foreign investor presence will contribute to the introduction of financial technology and innovation, thereby leading to higher market efficiency.
